Abstract

*This paper aims to describe *Tilia tomentosae-Carpinetum betuli* association. Knowledge of its structure, distribution in time and space is a desideratum that is required more and more in the sustainable development of human area and society. The scientific newness lies in approaching a habitat that wasn't explored and in the result achieved, which involved the identification and the characterization of some endemic species and associations (*Ruscus aculeatus*, *Cephalanthera longifolia*).*

Key words: surveys, association, phytocoenosis, ecological factors, floristic elements, life forms.

INTRODUCTION

This association is represented by forests, representing the largest vegetable formation from Lăzăreni Hills. They are located in the western Romania, in south central part of Bihor County, between Crișul Repede River to north and Crișul Negru River to south. Pop, Gr., (2005), (Fig.1).

In the research-documentation of this paper, was used information taken from the site, from specialty papers. Among the specialty works, we should note those about the climate regime Dragotă, C., (2006), relief Posea, Gr., (1997), soils Sabău, N., Domuța, C., Berchez, O., (2002) etc.

Fig. 1 Geographical location map of Lăzăreni Hills
Adaptation after Gr. Pop (2005)

MATERIALS AND METHODS

The projection of this vegetation study, realized in Lăzăreni Hills was based on own researches, observations and notes made on site during the years 2008-2010. After 72

field works, the botanical material was collected for the herbarium, totalizing a number of 384 species.

Taxons identified on site were harvested on plates and arranged in the herbarium. Taxons were identified based on specialty determiners from the volumes „Flora ilustrată a României” by V. Ciocârlan (1988,1990) and of International Code of Botanical Nomenclature (Code de Tokyo, 1993) etc.

In parallel with the collection of the material for herbarium the specialty literature was studied, both the general one and that which directly refers to the habitat studied. Pop, I., (1967), Pop, I., (1968), Mohan, Gh., Ardelean, A., Georgescu, M., (1993), Ardelean A, (1999), Burescu P., Cheregi V., (2002), Burescu P., Doniță N., Burescu L.,(2002), etc.

To the particularities of vegetation carpet from our country, we used the phytosociological research method of the European Central School, based on the principles and methods elaborated by J. Braun-Blanquet (1964) and adapted by A. Borza, N. Boșcaiu (1965).

Sample surfaces (Fig. 2), homogeneous from florist and physiognomical point of view were chosen from the phytocoenosis of lime arbors with yoke elm, with the size of 400 m².

Fig. 2 *Tilia tomentosae-Carpinetum betuli*, Doniță 1968

The summary table (Table 1) includes information about the species entering in the flora composition of the association, the biological form, the flora element, ecological factors (humidity, temperature, chemical reaction of soil), the order number of the survey, the altitude (m.s.m.), exposition, tilt, herbaceous layer cover (%) and the surface (m²). At the bottom of the table was registered the locality where it was met and the date of surveys.

Participation of each species to the association table was made with the help of the index of abundance–dominance after the evaluation system of J. Braun-Blanquet and J. Pavillard (1928). To the end of the table was registered and calculated the constancy (K), the phytocenotical index whose class is between I-V and expresses the coenetic fidelity degree of each species to the ambiance of the association's phytocoenoses.

For ordering and grouping the species in the association table, to superior cenotaxons, sub-alliance, alliance, order and class were considered the traditional ecological and floral systems of the authors Braun-Blanquet, J., (1964), Braun-Blanquet, J., Pavillard, J., (1928), Tüxen, R., (1955), Elleemberg H., (1974), Soó, R., (1964-1980) and also the works recently appeared belonging to the signatories of the authors Täuber, F., (1992), Mucina L., Grabherr G., Ellmaner T., (1993), Pott R., (1995), Borhidi A., (1996), Oprea, A., (2005) etc. From the 32 surveys made, 10 were selected, being grouped in an association table.

RESULTS AND DISCUSSIONS

In order to register the phytocenological and ecological study of the association *Tilia tomentosae-Carpinetum betuli*, we graphically represented, in the form of spectra, the repartition of biological forms, floral elements and ecological factors in phytocoenosis analyzed.

This association can be seen under the form of small islands in the area of the forests from Querco-Fagetea class. In this association, are mostly grouped mesohydrophilic phytocoenosis, frequently common in the hills area and on the plateau from the south-eastern Romania. Soils are brown, rarely brown acid, with clay and sandy texture.

From the life forms spectrum (Fig.3) it results the dominance of hemicryptophytes (48.7%), followed by megaphanerophytes (18.7%), which are almost equal to geophytes (17.5%).

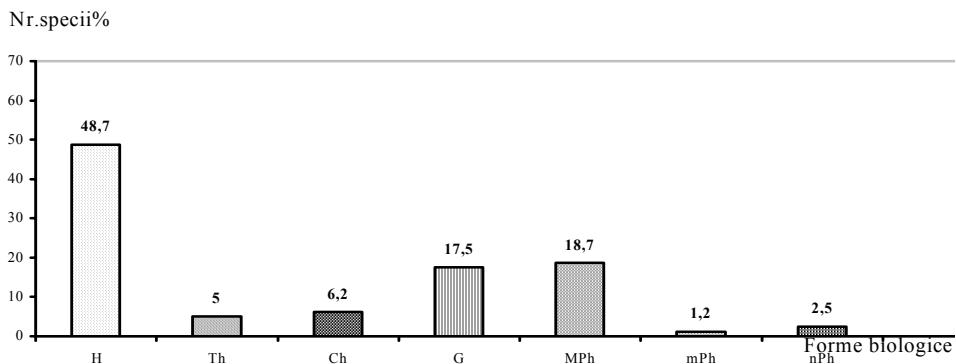

Fig.3. Life forms spectrum of the association *Tilia tomentosae-Carpinetum betuli* from Lăzăreni Hills, we have: H=hemicryptophytes; Th=therophytes; Ch=camephytes; G=geophytes; MPh=megaphanerophytes; mPh=mesophanerophytes; nPh=nanophanerophytes.

Floristic elements spectrum (Fig. 4), highlights the remarkable weight of European species (35%), in regard to Euro-Asiatic species (31.2%).

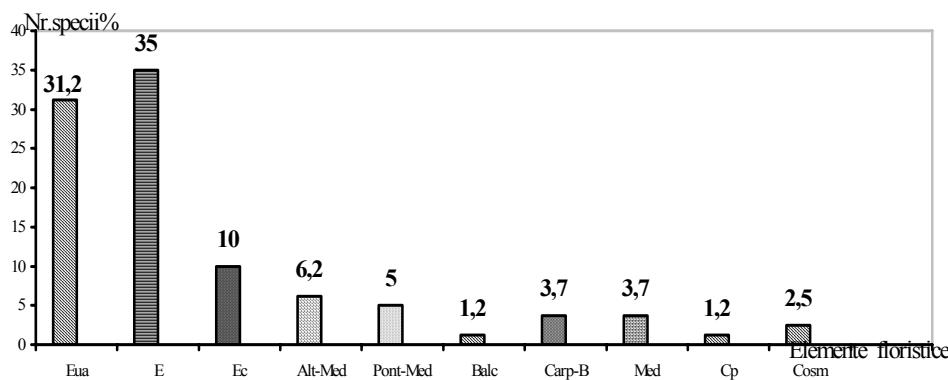

Fig.4. Floristic elements spectrum of *Tilia tomentosae-Carpinetum betuli*-association—from Lăzăreni Hills, we have: Eua=Euro-Asiatic; E=European; Ec=Central European; Alt-Med=Atlantic-Mediterranean; Pont-Med=Ponto-Mediterranean; Balc=Balkan; Carp-B=Carpathian-Balkan; Med=Mediterranean; Cp=Circumpolars; Cosm=Cosmopolitans.

The phytocoenosis analysis under the aspect of main ecological factors (Fig. 5) highlights the predominance of mesophyle species (38.7%) and of xero-mesophyle species (26.2%). The temperature is highlighted by micro-mesothermal plants (65%), and chemical reaction of neutrophile-acid 40% and weakly neutrophile-acid (37.5%).

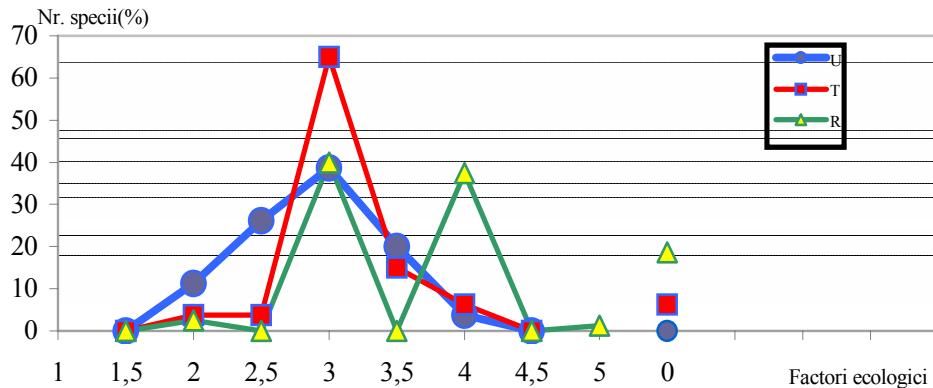

Fig. 5 Ecological factors spectrum of the association *Tilia tomentosae-Carpinetum betuli* from Lăzăreni Hills, we have: U=humidity; T=temperature; R= chemical reaction of soil.

The importance of the association *Tilia tomentosae-Carpinetum betuli* is given by the presence, in the undergrowth layer, of the evergreen frutex *Ruscus aculeatus* (Fig. 6). Popularly called "Bur", it is declared a natural monument and it is protected by law.

In our country, it is located on the rocky and dried coasts in the underwood from Oltenia and Banat, sporadic in the western Transylvania, Dobrogea (Niculițel Forest, Mangalia, above the thermal baths), Muntenia Plain. In the work „Rezervații și monumente ale naturii din România” of Mohan, Gh., Ardelean, A., Georgescu, M., (1993), it is mentioned, with other rare and endemic species, in reservations from Valea Mare (Caraș-Severin county) and Comana Forest (Giurgiu county).

In this association, in the herbaceous layer, we also see a beautiful forest orchid *Cephalanthera longifolia* (Fig.7) rare, on the red list, which is protected by law, too.

Fig.6 *Ruscus aculeatus* L. - on Betfia Valley-Betfia locality

Fig. 7 *Cephalanthera longifolia* L. - near the observer, on Betfia Valley-Betfia locality.

Because to the warmer climate, *Ruscus aculeatus* Mediterranean plant, is also presented in Lăzăreni Hills, on coasts, abrupt and sunny slopes (under Șomleu Hill, Betfia Forest, Cordău Forest, Hidișel Hills, Boboștea Micănear Șauaie, Poiana Tășad Forrest).

The proportion and the distribution of *Ruscus aculeatus* frutex varies from a lot to another, having an uniform distribution, in small groups up to isolated ones.

After the study of the vegetation form Lăzăreni Hills were identified a series of issues, showing a high degree of endangerment of flora and vegetation from this area. In order to prevent the degradation and the reduction of natural surface, are required some proposals and suggestions:

- to large the area of Natura 2000 Site from Betfiei Hills;
- to establish some natural reservations which include the habitat of woody specia *Ruscus aculeatus* (forests from 1 Mai, Betfia, Copăcel, Cordău and in inslands, the forests from Șumugiu,etc.);
- to introduce some legislative measures in order to transform the forestries from production units and forestry exploitation in protection units;
- to co-inters local authorities and citizens in various actions in order to protect flora and vegetation from Lăzăreni Hills;

CONCLUSIONS

- Human impact on vegetation from this space took various types and forms, among which stands out: burning of vegetation, overgrazing, deforestation and not at least air and waters pollution.
- The result of human impact is that a large number of species, some of them having endemic value, disappeared or will disappear.
- Among floral species endangered to disappear, from Lăzăreni Hills, we mention: *Ruscus aculeatus*, *Poamogetus crispus*, *Ranunculus aquatilis*, *Cephalanthera longifolia*, *Cephalanthera damasonium*, *Plathanthera bifolia*, *Orhis morio*, *Cyperus fuscus*, *Cyperus flavescens*, *Echinochloa crus-galli*, *Najas minor*, etc.
