Abstract

This paper is a study of the pastoral value of Agrostis capillaris grassland in the area of Tăşad Hills, Bihor County. The study was carried out in order to optimize the use of grassland, to determine the correct biomass production and load with animals.

The determination of the pastoral value of grassland in the area of Tăşad Hills is important in the context of rural development, the preservation of biodiversity, the improvement of soil fertility and the provision of quality feed for animals.

The study of the pastoral value of the Agrostis capillaris grasslands was carried out between 2018 and 2019, with a number of 28 relevées being carried out. The pastoral value was determined individually for all the relevées, and finally an average pastoral value of the studied grassland was also determined.

The determination of the pastoral value of grassland at national level is useful in the context of carrying out pastoral planning, which are useful in the context of the increase in eligible grassland areas and the economic activities of livestock farming.

Key words: pastoral value, grasslands, optimization, qualitative index, species.

INTRODUCTION

Grassland is an essential element of sustainable farming systems that meet the demands of healthy and high-quality food.

In addition to the decisive role of providing animal feed, grassland has an important function in rural development and the environment, reflected by the preservation of biodiversity, improvement of soil fertility, nitrogen symbionts, hydrologic balance, flood and landslides prevention, atmospheric carbon storage, landscape quality and important cultural heritage.

Livestock systems based on the exploitation of grazing land are now facing growing food needs, as the production of feed produced on these areas keeps pace with the growing demands of meat, milk and climate change.

Recent publications on the study of grassland quality in Romania were carried out by Durău, Moisuc, 2006; Durău et al., 2008; Marușca, 1978, 2005, 2008, 2013; Moisuc et al. 2001; Pășcuț, 2017, 2018; Păcurar, Rotar, 2014.

MATERIAL AND METHOD

For the determination of the pastoral value of the studied grassland, floristic methods of appreciation have been used. The assessment of the participation of the component species and the floristic composition was made in combination with the phytosociological method and the pratological method. The phytosociological method makes use of an appreciation of the abundance and dominance (AD) of species on relevées of 100 m² at key representative points and is marked on a 6-step scale, namely: 5 (coverage average of 87.5%), 4 (coverage average of 62.5%), 3 (coverage average of 37.5%), 2 (coverage average of 17.5%), 1 (coverage average of 5%), + (coverage average of 0.5%), (Ivan, Doniță, 1975; Cristea et al., 2004). The pratological method consists in assessing the percentage participation of botanical components in biomass by economic groups: *Poaceae*, *Fabaceae*, other families, harmful-toxic species, wood species, and is the one used more widely in the study carried out.

The relevées were chosen in the characteristic fragments of the meadows depending on the nature and complexity of their horizontal and vertical structure.

To describe the vegetation as accurately as possible data were recorded on the habitat conditions under which this grassland is developed, namely: altitude, GPS coordinates, exposition, slope tilt, vegetation cover (%). Quantitative participation of each species was also recorded by setting the dominance and percentage (Table 1).

For the determination of the pastoral value the following formula was used as indicated by certain specialists, (Marușca et al., 2014):

$$V.P. = \sum PC(\%) \times IC / 5$$

where: V.P. – pastoral value indicator (0-100);

P.C. – participation in the grassy area (%),

I.C. – forage quality index.

The values of the feed quality index (IC) have been taken over from the work of Rotar et al. (2009) și Marușca et al. (2012, 2014).

After the relevées had been carried out on the field and the percentage share of each species's participation in the floristic composition had been determined, the feed quality index was passed, with values from 0 (without fodder value) to 5 (with excellent fodder value). After determining the pastoral value indicator, grasslands can be appreciated as follows: 0-5 (degraded grassland), 5-15 (very weak), 15-25 (weak), 25-50 (medium), 50-75 (good), 75-100 (very good) (Marușca et al., 2014).

The scientific name of the species identified on the ground was adopted in accordance with the expert work developed by Ciocârlan (2009) and Sârbu et al., 2013.

RESULTS AND DISCUSSION

The grassland of *Agrostis capillaris* occupy the largest surface in the Tăşad Hills area. This grassland is found on lands with different expositions, with slope of 6.87-20.57%, at altitudes between 200 m and 440 m. The vegetation of this grassland is mainly occupied by grass species (58-97%), there also being some woody species, especially shrubs (3-42%). The floristic composition of this grassland is rich in species (161 species) (Table 1). The grassy vegetation is largely composed of *Poaceae* species (69.11%, 25 species), where the dominant is *Agrostis capillaris* (54.29%), other species being present well such as *Lolium perenne* (3.68%), *Festuca rubra* (2.46%), *Dichanthium ischaemum* (2.32%), *Holcus lanatus* (1.11%), *Festuca pratensis* (0.89%), *Cynosurus cristatus* (0.79%), *Festuca valesiaca* (0.75%), *Festuca rupicola* (0.64%), *Cynodon dactylon* (0.5%), *Poa pratensis* (0.5%), *Anthoxanthum odoratum* (0.5%). There are also *Fabaceae* species (5.39%, 13 species), of which the most common are *Trifolium repens* (2.14%), *Lotus corniculatus* (1.61%), *Trifolium campestre* (0.53%), *Trifolium pratense* (0.5%). The numerical weight is held by the species from other families of herbaceous plants (88 species), these having an overall coverage of 8.11%, the following species being highlighted *Thymus glabrescens* (1.68%), *Juncus effusus* (1.14%), *Hieracium pilosella* (1%), *Daucus carota* (0.75%), *Leontodon hispidus* (0.57%). Toxic and harmful species have a weight of 17.4% (18 species), of which we can highlight *Euphorbia cyparissias* (9.21%), *Pteridium aquilinum* (5.82%), *Eryngium campestre* (1.61%) (Table 1).

The woody vegetation has a significant share in some grassland, occupying 16.8% (17 species) in the studied relevées. From the shrubs the following stand out *Rubus sulcatus* (7.29%), *Prunus spinosa* (2.04), *Crataegus monogyna* (1.21%), *Rosa canina* (1%). In some relevées, the occurrence of invasive youth from tree species was found, these are: *Betula pendula* (2.25%), *Populus tremula* (1.29%), *Robinia pseudacacia* (1.25%) (Table 1).

Agrostis capillaris is a valuable grass forage, with a high degree of consumability, with a qualitative index of 3. In general, the pastoral value of this grassland is medium and good, reaching a production of 10-15 t/ha green mass and having a grazing capacity of 1-1.2 large cattle unit/ha, for pastures with good pastoral value and a production of 5-7.5 t/ha green mass and a grazing capacity of 0.5-0.8 large cattle unit/ha for grasslands with medium pastoral value.

where: VP – pastoral value; PC – participation in the grassy area of each species (%); IC – forage quality index of each species.

Date of relevées: 1-8 (15.09.2018); 9-12 (18.09.2018); 13-16 (25.09.2018); 17-23 (01.09.2019); 24-28 (05.09.2019).

CONCLUSIONS

In the area under study, considering pastoral value, *Agrostis capillaris* grassland of medium productivity (20 relevées) and good productivity (8 relevées), were found.

The pastoral value of all studied grassland is medium (V.P.=45.92). A significant proportion of toxic and harmful species is observed in some relevées (*Eryngium campestre*, *Pteridium aquilinum*, *Eryngium campestre*, *Ranunculus polyanthemos*, *Cardus acanthoides*, *Ambrosia artemisiifolia*), this decreases their pastoral value. For the removal of toxic and harmful species from the studied grassland, work is needed to combat mechanical, chemical and biological methods, overgrowing the remaining gaps.

The woody species are also present in this grassland in shrub or invasive form of tree species, works to combat them and the overgrowth of the remaining gaps being also necessary.

The overgrowth of the grasslands will be carried out with local species of plants, wishing to preserve their natural composition.

Fertilization work with organic and chemical fertilizers are required to increase the productivity of the grassland studied.

Due to the small number of animals that graze on these pastures in the future, some of them will be covered by woody vegetation, receiving another destination.
